

Plant traits in relation to environment:

Adaptation and community assembly

1) Plant traits along environment gradients

- Trait-environment relationships of communities vs. species
- Evolutionary divergences and adaptation

2) Limiting similarity and community assembly

3) Synthesis!

I. SCLEROPHYLLOUS WOODLAND IN GENERAL.

WHILST the districts referred to in the previous chapter resemble the tropics climatically in the coincidence of the rainy season with high temperatures, and accordingly possess a vegetation similar to that of the tropics, this likeness entirely ceases in countries where the precipitations coincide with low temperatures and at the same time the hot season is quite rainless or nearly so. Here the totally different aspect of the vegetation corresponds to the sharp difference in climatic conditions, and finds no analogy within the tropics. *The mild temperate districts with winter-rain and prolonged summer-drought are the home of evergreen xerophilous woody plants, which, owing to the stiffness of their thick, leathery leaves, may be termed sclerophyllous woody plants.*

The climatic districts belonging to this group are the littoral countries of the Mediterranean Sea, the south-west extremity of Africa, South-West Australia and the greater part of South Australia, Central Chili, and the greater part of the coastland of California. In all these widely separated countries the vegetation bears essentially the same stamp, in spite of deep-seated difference in the composition of the flora. It is dominated by sclero-

“All [these] districts are the home of evergreen xerophilous woody plants which ... may be termed *sclerophyllous*.”

Schimper, 1903

Limiting similarity among coexisting species

(MacArthur & Levins 1967)

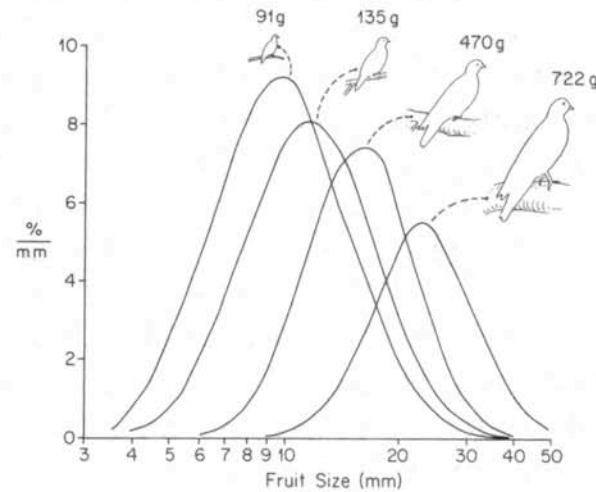

Figure 35-2

Activity curves of two species along a single resource dimension showing niche breadth, the distance between the centers of the niches, and niche overlap.

Body size ratios: the '1.3 rule'

(Hutchinson, 1959)

hypothesized patterns:

- 1) minimum size ratios
- 2) constant size ratios across an entire assemblage
- 3) large ratios on islands due to intense competition

Diamond 1975

Limits to similarity among coexisting competitors

Nature, 270: 660-661, 1977

from Henry S. Horn and Robert M. May

Fig. 1 The conventional ensemble of recorders, whose lengths roughly obey the '1 : 3 ratio rule'.

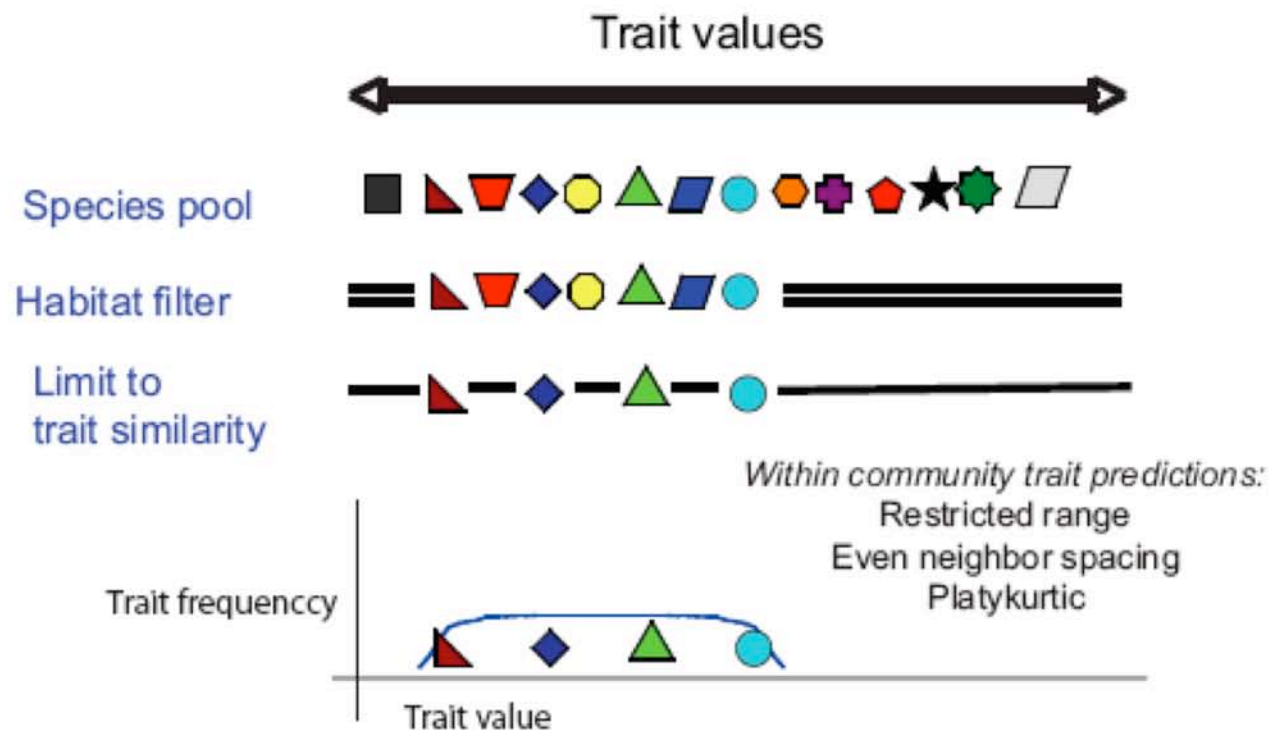

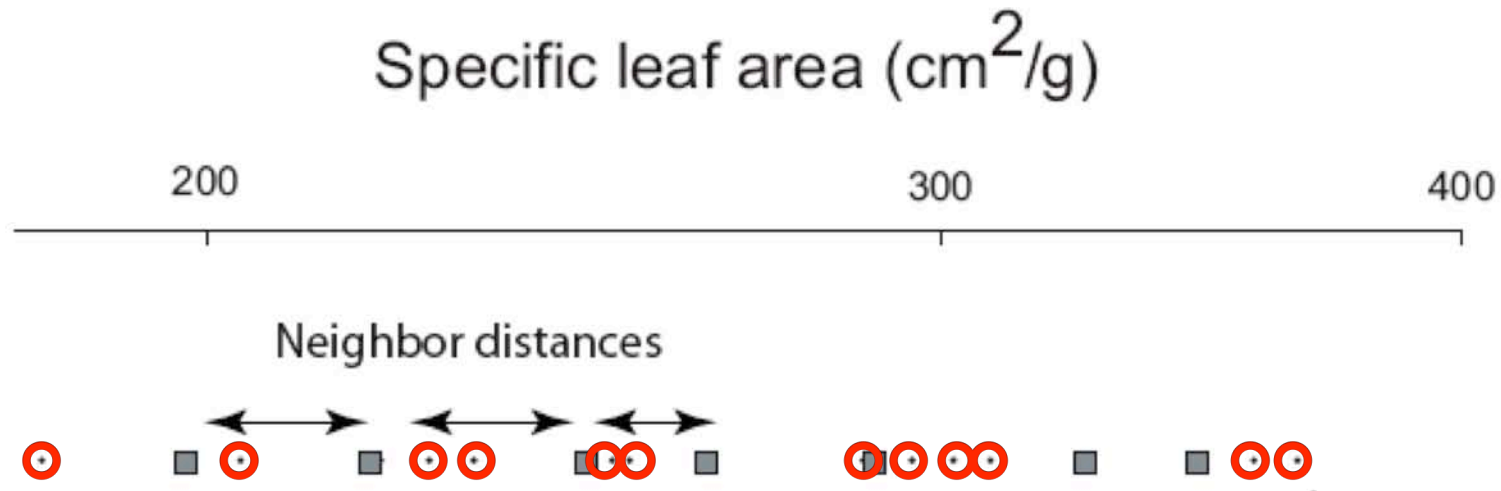

Figure 1: A hypothesis for assembly effects on within community trait distribution (following Diaz et al., 1998; Weiher et al., 1998). The strength of the habitat filter and limiting similarity is expected to depend on the identity of the trait in combination with the particular abiotic conditions at a site. Note that the variance of trait values is affected by both processes.

even spacing = low standard deviation of
neighbor distances

squares: species present in community

red circles/dots: other species in local 'pool' that
could be present in community

Histogram of observed plus null values for sdND

Cornwell data set: Woody plant species of coastal CA, across gradients in elevation and insolation

Sampling: 44 20 x 20 m plots randomly located across 5 vegetation types; relative abundance of all woody plants sampled

Species: 54 species total, 3-18 spp. per plot

Traits: 14 leaf, stem and root traits measured for (almost) all spp.; SLA and leaf size measured in situ in each plot

Will Cornwell, post-doc, Univ. British Columbia, wcornwell@gmail.com

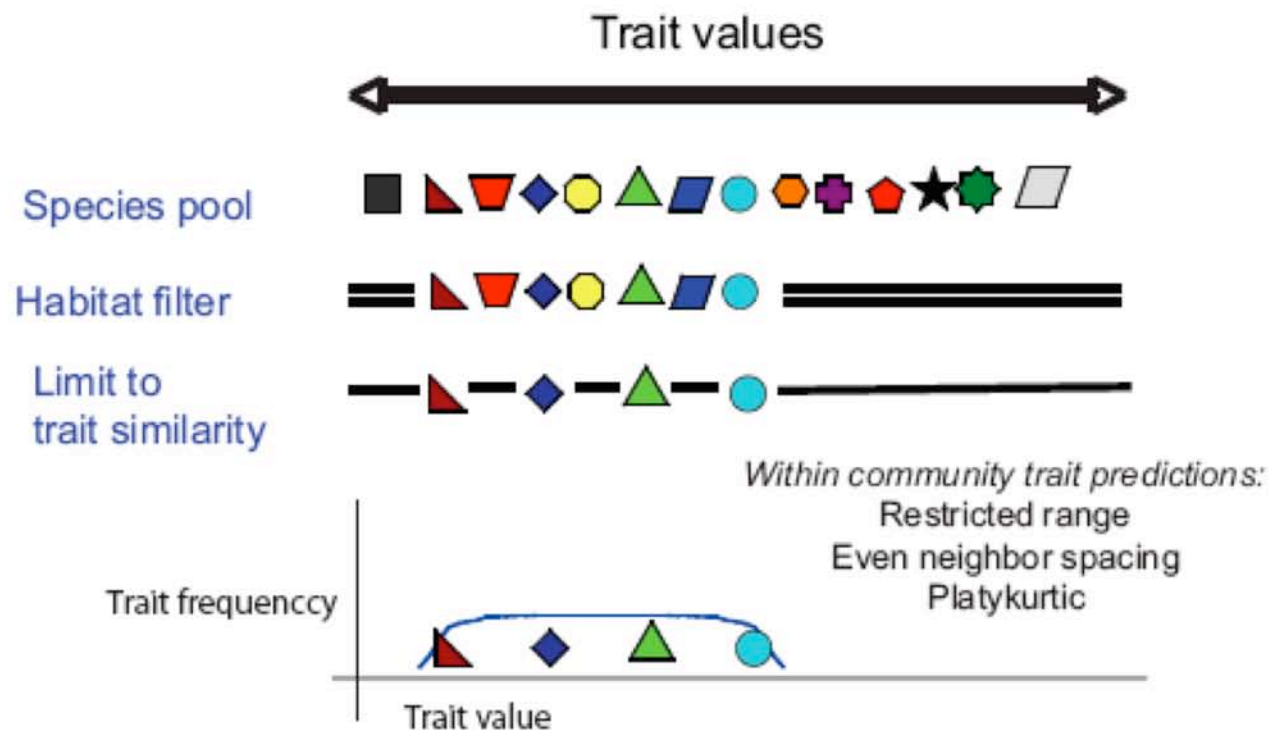

Figure 1: A hypothesis for assembly effects on within community trait distribution (following Diaz et al., 1998; Weiher et al., 1998). The strength of the habitat filter and limiting similarity is expected to depend on the identity of the trait in combination with the particular abiotic conditions at a site. Note that the variance of trait values is affected by both processes.

Test for restricted range

triangles: observed SLA range in each of 44 plots

circles: expected range based on 999 null communities of same diversity, drawn from full species pool

Even spacing in trait space—limiting similarity

Spacing more even than expected ($P=0.02$)

Tests for limiting similarity (Stubbs and Wilson 2004)

- 1,4) Mean nearest-neighbor distance (1: multivariate; 4: single characters) (+)
- 2) Min/Max link distance on minimum spanning tree (+)
- 3) Minimum nearest-neighbor distance (+)
- 5) Weighted deviance (+?)
- 6) Variance of NN dist/range (-)
- 7) Mean niche overlap (-)
- 8) Maximum overlap (-)
- 9) Weighted adjacent neighbor overlap (-)
- 10) Variance in adjacent neighbor overlap (-)

Soil Moisture

Synthesis of 'convergence' and 'limiting similarity' perspectives

- Individual traits can show both a limited range of values, and even spacing within that range
- One set of traits exhibits convergence and another exhibits even spacing
